Abstract-- Electrochemical corrosion behavior, mechanical, electrical and thermal properties of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($\text{X}=\text{Cu, Se, In, Al and Zn, } x=2$) rapidly solidified alloys have been investigated. X-ray diffraction analysis show that, $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys have lines corresponding to rhombohedral Bi phase, tetragonal Sn phase, face centered cubic Pb phase, hexagonal Cd phase and Pb_7Bi_3 intermetallic phase with different intensity, broadness and position. Corrosion rate of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy in 0.5M HCl decreased after adding Cu, Se, In, Al and Zn contents. Elastic modulus of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy increased after adding Cu, Se, In, Al and Zn contents. Vickers hardness and internal friction of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy decreased after adding Cu, Se, In, Al and Zn contents. Wetting behavior of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy varied after adding Cu, Se, In, Al and Zn contents. The $\text{Bi}_{48}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{In}_2$ alloy has lowest melting temperature (69 °C) for shielding blocks used in radio therapy.

Index Term-- corrosion current, corrosion rate, Vickers hardness, elastic modulus, internal friction, microstructure, wettability

1. INTRODUCTION

Fusible alloys are one such category of materials, which have attracted the attention of scientists and technologists all over the world. Because fusible alloys expand and push into mould detail when they solidify, they are excellent for duplication and reproduction processes. This characteristic of expansion and/or non-shrinkage, combined with low melting temperature and ease of handling, are the major reasons for their extensive use. Microstructure, electrical resistivity, hardness, creep indentation, mechanical and thermal properties of Bi-Sn-Cd-Pb and Bi-Pb-Sn-Cd-Sb fusible alloys have been investigated [1-6]. The results show that, all measured properties are greatly affected by alloys composition and preparation method, rapid quenching method. Also these results gave an indicator for the most prominent alloys for various applications such as solder, bearing and shielding blocks used in radio therapy. Structure, wettability, melting point, electrical and mechanical properties of Sn-Zn-Bi-Cu-In, Sn-In, Sn-In-Ag, Sn-Zn-Ag-In, Sn-Zn-In, Bi-Sn, Sn-Bi-In and Sn-Ag lead free solder alloys have been studied and analyzed [7-12]. The results show that, these alloys have required properties for solder applications. The aim of present work is to study and analyze the effect of adding alloying elements such as Zn, Se, In, Cu and Al on microstructure,

electrical resistivity, elastic modulus, internal friction, wetting behavior, melting temperature and corrosion behavior of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ rapidly solidified alloy.

2. EXPERIMENTAL WORK

In this work $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($\text{X}=\text{0, Cu, Se, In, Al and Zn, } x=0 \text{ or } 2$) alloys were used. These alloys were molten in the muffle furnace using high purity, more than 99.95%, bismuth, lead, tin, cadmium and alloying elements (Cu, Se, In, Al and Zn). The resulting ingots were turned and re-melted several times to increase the homogeneity of the ingots. From these ingots, long ribbons of about 3-5 mm width and ~ 70 μm thickness were prepared as the test samples by directing a stream of molten alloy onto the outer surface of rapidly revolving copper roller with surface velocity 31 m/s giving a cooling rate of 3.7×10^5 k/s. The samples then cut into convenient shape for the measurements using double knife cutter. Microstructure of used samples was studied using a Shimadzu x-ray diffractometer (Dx-30, Japan) and scanning electron microscope JEOL JSM-6510LV, Japan. Also electrical resistivity and DTA thermographs were obtained by a conventional double bridge method and SDT Q600 V20.9 Build 20 instrument with heating rate 10 °k/min. A digital Vickers micro-hardness tester, (Model-FM-7-Japan), was used to measure Vickers hardness values of used alloys. Internal friction Q^{-1} and the elastic constants of used alloys were determined using the dynamic resonance method [13-15].

The electrochemical experiments were done using a conventional three-electrode cell assembly at the selected temperatures. The carbon steel electrode of size (1 x 1 x 0.2 cm^3) with an exposed area of 1 cm^2 and the rest being covered with extra pure paraffin wax was used as working electrode. The cell consisted of a platinum counter electrode and a calomel electrode as the reference electrode. The working electrode was polished successively with different grades of emery paper (320-2000), washed with water and then degreased in acetone. All the tests were performed under unstirred conditions without deaeration. The polarization studies were performed using Gamry Potentiostat/Galvanostat with a Gamry framework system based on ESA 300. Gamry applications include software DC105 for corrosion measurements, and Echem Analyst version 5.5 software packages for data fitting. The working electrode was

immersed in the acid solution and the constant steady-state (open circuit) potential was recorded when it became virtually constant. The polarization studies were carried out over a potential of +250 to -250 mV with respect to the open circuit potential at a scan rate of 5 mV s^{-1} . The linear Tafel segments of the anodic and cathodic curves were extrapolated to obtain corrosion potential (E_{corr}) and corrosion current density (j_{corr}).

3. RESULTS AND DISCUSSION

3.1 Microstructure

Fig. 1 shows x-ray diffraction patterns of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($X=0, \text{Cu, Se, In, Al and Zn, } x=0 \text{ or } 2$) rapidly solidified alloys. From x-ray analysis, $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys have lines corresponding to rhombohedral Bi phase, tetragonal Sn phase, face centered cubic Pb phase, hexagonal Cd phase and hexagonal Pb_7Bi_3 intermetallic phase with different intensity, broadness and position. That is mean that, adding alloying elements such as Cu, Se, In, Al and Zn caused a change in Bi- Pb- Sn- Cd alloy matrix microstructure such as crystallinity which is related to intensity of the peak, crystal size which is related to full width half maximum and the orientation which is related to the position of the peak. That is because these alloying atoms, Cu, Se, In, Al and Zn, dissolved in alloy matrix forming solid solution/ or cluster from these atoms which affected on all measured properties. Also x-ray diffraction patterns of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($X=0, \text{Cu, Se, In, Al and Zn, } x=0 \text{ or } 2$) alloys after corroded in 0.5 M HCl are shown in Fig. 2. X-ray analysis of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys show that, intensity of the peak, full width half maximum and the position of the peak changed after corroded in 0.5 M HCl.

Lattice parameters, (a and c), and unit volume cell of β - Sn phase in $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys were determined from equations (1) and (2) and then listed in Table I.

$$\frac{1}{d^2} = \frac{(h^2+k^2)}{a^2} + \frac{l^2}{c^2} \quad (1)$$

$$V = a^2c \quad (2)$$

Lattice parameters and unit volume of β - Sn changed after adding Cu, Se, In, Al and Zn elements to $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy. That is because Cu, Se, In, Al and Zn atoms dissolved in matrix alloy forming solid solution/ or cluster from these atoms.

Scanning electron micrographs, SEM, of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($X=0, \text{Se, Cu and Zn, } x=0 \text{ or } 2$) alloys before and after corroded in 0.5 M HCl are shown in Fig. 3. SEM analysis of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($X=0, \text{Se, Cu and Zn, } x=0 \text{ or } 2$) alloys show that, heterogeneity structure due to micro-segregation or different chemical reaction of these atoms after corroded in 0.5 M HCl.

3.2 Electrical properties

Electrical resistivity of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy varied after adding Cu, Zn, Al, In and Se elements as seen in

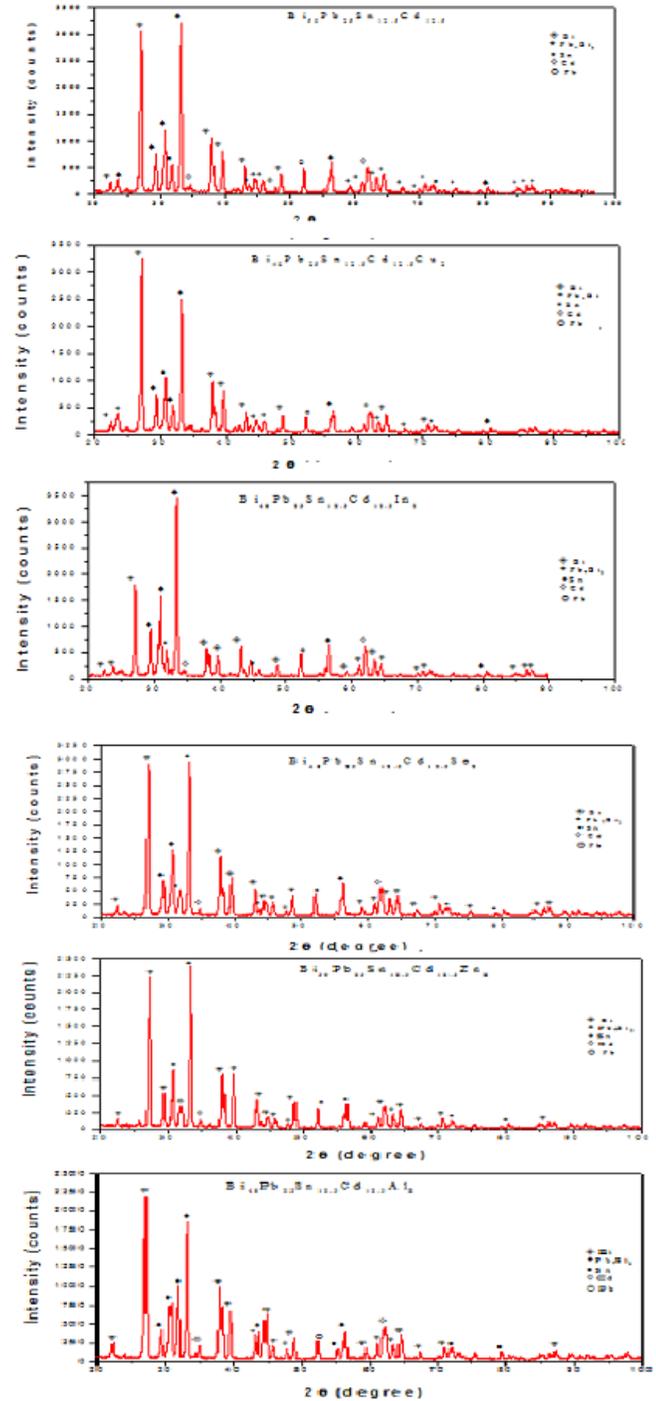

Fig. 1. X-ray diffraction patterns of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys

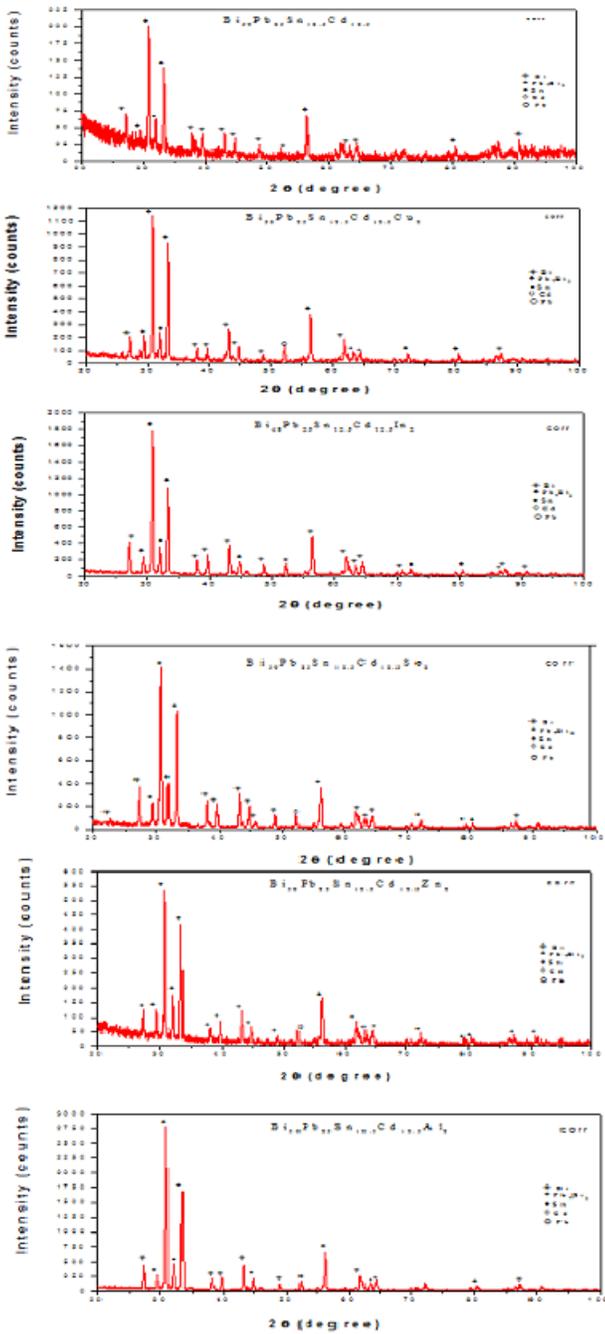

Fig. 2. X-ray diffraction patterns of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys after corroded in 0.5 M HCl

Table II. That is because these alloying atoms, Cu, Zn, Al, In and Se, dissolved in matrix alloy formed solid solution/ or cluster of these atoms play as a scattering center for condition electrons besides formed phases. Fig. 4 shows the resistivity of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys versus temperature. The resistivity of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys increased with increasing temperature.

The temperature coefficient of electrical resistance (T.C.R) for a given temperature change is a structure-sensitive

Electrical resistivity and T.C.R of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys

Alloys	Resistivity $\mu\Omega.cm$	T.C.R $\times 10^{-3} \text{ K}^{-1}$
$Bi_{50}Pb_{25}Sn_{12.5}Cd_{12.5}$	300	1.55
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Cu_2$	281	1.5
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Zn_2$	198	0.73
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Se_2$	467	0.84
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}In_2$	465	0.92
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Al_2$	293	0.54

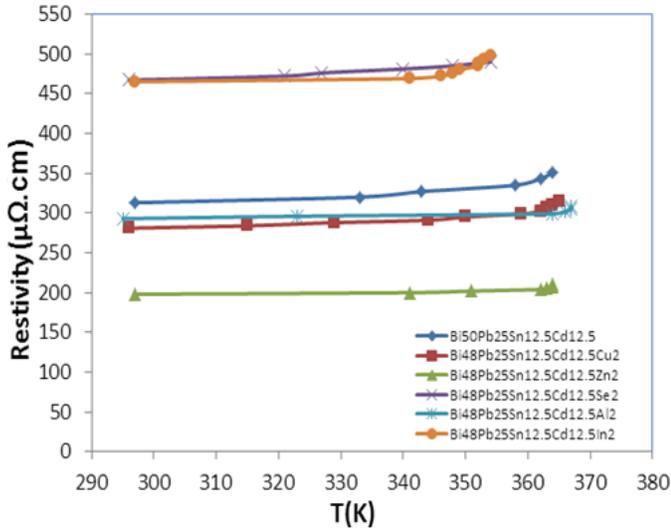

Fig. 4. Resistivity of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x alloys versus temperature

property varying depending on composition by the same law as electrical conductivity, i.e. proportional to (1/ρ). Temperature coefficient of electrical resistance of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy decreased after adding Cu, Zn, Al, In and Se contents as shown in Table II

3.3 Thermal properties

3.3.1 Melting point and pasty range

Melting temperature is very important for industrial and medicine applications. Fig. 5 shows thermo-graphs of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x alloys. The analysis show that, a little variation in exo-thermal peak of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy after adding Cu, Zn, Al, In and Se contents. The Bi₄₈Pb₂₅Sn_{12.5}Cd_{12.5}In₂ alloy has lowest melting temperature, 69 °C, as shown in Table III.

The pasty range is the difference between solidus and liquidus points. The pasty range of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x (X=0, Cu, Zn, Al, In and Se & x=2) alloys are listed in Table III. The pasty range value of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy varied after adding Cu, Zn, Al, In and Se contents.

3.3.2 Wetting behavior

Wettability is an importance property of to the manufacturing or product engineer. Indeed, wettability is defined as the tendency for a liquid metal to spread on a solid surface. Wettability is quantitatively assessed by the contact angle formed at the surface. The contact angles of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x (X=0, Cu, Zn, Al, In and Se & x=2) alloys on pure Cu substrate in air are shown in Table IV. The results show that, no significant change in contact angle of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy after adding Zn, Se, In and Al contents. But adding Cu element caused a significant increase in contact angle of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy.

Table III
Melting temperature and pasty range of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x alloys

Alloys	Melting point °C	Pasty range °C
Bi ₅₀ Pb ₂₅ Sn _{12.5} Cd _{12.5}	75.22	18.92
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Zn ₂	75.19	19.53
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Se ₂	75.74	24
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} In ₂	69.32	16.22
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Al ₂	75.13	17.07

Table IV
Contact angles of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x alloys on pure Cu substrate in air

Alloys	Contact angle θ°
Bi ₅₀ Pb ₂₅ Sn _{12.5} Cd _{12.5}	43.5±2.2
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Cu ₂	53±3
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Zn ₂	44±2.7
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Se ₂	45±3
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} In ₂	41.5±2.1
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Al ₂	40±2

3.4 Elastic moduli

The elastic constants are directly related to atomic bonding and structure. It is also related to the atomic density. Values of bulk modulus, B, and shear modulus, μ, of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x (X=0, Cu, Se, In, Al and Zn, x=0 or 2) alloys are calculated using the standard equations after calculating the Young's modulus, E, using the dynamic resonance method. Elastic modulus of Bi₅₀Pb₂₅Sn_{12.5}Cd_{12.5} alloy increased after adding Cu, Se, In, Al and Zn as shown in Table V. That is because these alloying elements changed matrix alloy structure such as dissolved atoms formed solid solution/or cluster of these atoms as seen in SEM and x-ray analysis. These change increased bonding strength which related to elastic modulus.

Table V
Elastic moduli of Bi_{50-x}Pb₂₅Sn_{12.5}Cd_{12.5}X_x alloys

Alloys	E (GPa)	B GPa	μ GPa
Bi ₅₀ Pb ₂₅ Sn _{12.5} Cd _{12.5}	19.6±2.15	22.92	7.22
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Cu ₂	21.76±2.9	25.54	8.01
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Zn ₂	21.39±2.95	24.74	7.89
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Se ₂	30.16±3.59	35.28	11.11
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} In ₂	23.55±2.58	31.38	8.56
Bi ₄₈ Pb ₂₅ Sn _{12.5} Cd _{12.5} Al ₂	29.64±2.8	34.76	10.91

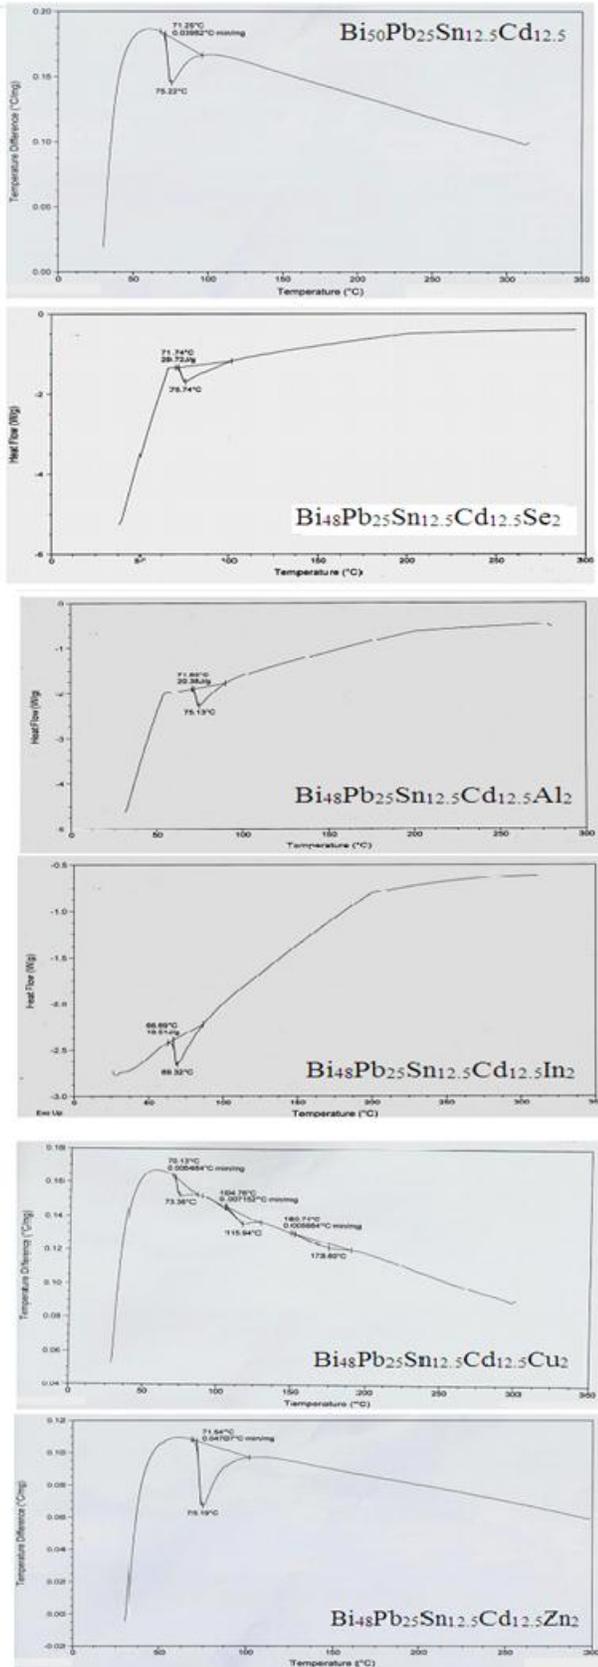

Fig. 5. DSC thermo-graphs of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys

3.5 Vickers Microhardness and minimum shear stress

The hardness is the property of material which gives it the ability to resist being permanently deformed when a load is applied. Vickers hardness of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ ($X=0, Cu, Se, In, Al$ and $Zn, x=0$ or 2) alloys at 10 gram force and indentation time 5 sec are shown in Table VI. Vickers hardness of $Bi_{50}Pb_{25}Sn_{12.5}Cd_{12.5}$ alloy decreased after adding Cu, Se, In, Al and Zn contents. That is because these alloying atoms dissolved in matrix alloy and stick in grain boundary or between matrix atoms affected on bonding strength of the alloy. The minimum shear stress (τ_m) value of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ ($X=0, Cu, Se, In, Al$ and $Zn, x=0$ or 2) alloys was calculated using the equation [14]:-

$$\tau_m = \frac{1}{2} H_v \left\{ \frac{1}{2} (1 - 2\nu) + \frac{2}{9} (1 + \nu) [2(1 + \nu)]^{\frac{1}{2}} \right\}$$

Where ν is Poisson's ratio of the elements in the alloy

Table VI
Vickers hardness and minimum shear stress of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys

Alloys	H_v (Kg/mm ²)	μ_n (Kg/mm ²)
$Bi_{50}Pb_{25}Sn_{12.5}Cd_{12.5}$	12.85±1.86	4.24
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Cu_2$	7.13±1.16	2.35
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Zn_2$	12.27±0.4	4.05
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Se_2$	4.55±0.4	1.5
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}In_2$	4.19±0.87	1.38
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Al_2$	4.86±0.83	1.61

3.6 Internal friction and thermal diffusivity

Internal friction is an energy loss or dissipation in a stressed material not due to external process. Internal friction is a useful tool for the study of the structural aspects of fusible alloys. Resonance curves of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ ($X=0, Cu, Se, In, Al$ and $Zn, x=0$ or 2) alloys are shown in Fig. 6. Also calculated internal friction and thermal diffusivity values are presented in Table VII. Internal friction of $Bi_{50}Pb_{25}Sn_{12.5}Cd_{12.5}$ alloy decreased after adding Se, In, Al and Zn contents.

Table VII
Internal friction and thermal diffusivity of $Bi_{50-x}Pb_{25}Sn_{12.5}Cd_{12.5}X_x$ alloys

Alloys	$Q^{-1} \times 10^{-3}$	$D_{th} \times 10^{-8}$ (m ² /sec)
$Bi_{50}Pb_{25}Sn_{12.5}Cd_{12.5}$	68.1±4.8	4.09
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Cu_2$	76.11±5	7.52
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Zn_2$	35±2.8	7.48
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Se_2$	49.4±3.9	17.72
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}In_2$	45.45±3.8	11.69
$Bi_{48}Pb_{25}Sn_{12.5}Cd_{12.5}Al_2$	49.37±4.3	11.43

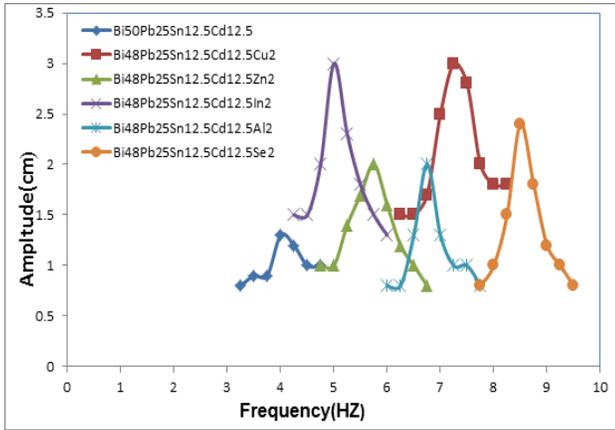

Fig. 6. Resonance curves of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys

3.7 Electrochemical corrosion behavior

Fig. 7 shows electrochemical polarization curves for $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ and $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($\text{X}=\text{Cu, Se, In, Al}$ and $\text{Zn, } x=2$) alloys in 0.5M HCl. From this figure, the corrosion potential of these alloys exhibited a negative potential. Also the cathodic and the anodic polarization curves showed similar corrosion trends. The corrosion potential (E_{Corr}), corrosion current (I_{Corr}) and corrosion rate (C.R) of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ and $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($\text{X}=\text{Cu, Se, In, Al}$ and $\text{Zn, } x=2$) alloys in 0.5M HCl are listed in Table VIII. The results show, corrosion current and corrosion rate of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy in 0.5M HCl decreased after adding Cu, Se, In, Al and Zn. Also very little variation was happen in corrosion potential of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy by adding these alloying elements. That is because adding Cu, Se, In, Al and Zn to $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy caused microstructure changed which affected on microsegregation and the reactivity of formed phases and other atoms with HCl solution. The $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{Al}_2$ alloy has lowest corrosion current and corrosion rate values.

Table VIII
Electrochemical parameters of $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ alloys

Alloys	E_{corr} mV	I_{corr} $\mu\text{A cm}^{-2}$	β_a mV dec^{-1}	β_c mV dec^{-1}	C. R mpy

$\text{Bi}_{48}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{In}_2$	232.7	53.49	40.98	282.2	1.82	2.618	286.3
$\text{Bi}_{48}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{Al}_2$	270.8	67.85	48.82	378.7	1.85	2.492	40.23
$\text{Bi}_{48}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{Zn}_2$	205.9	59.41	49.87	364.8	1.81	1.255	364.8

EFM is a non-destructive corrosion measurement technique. In which current responses due to a potential perturbation by one or more sine waves are measured at more frequencies than the frequency of the applied signal. The results of EFM experiments are a spectrum of current response as a function of frequency. The intermodulation spectrum of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ and $\text{Bi}_{50-x}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{X}_x$ ($\text{X}=\text{Cu, Se, In, Al}$ and $\text{Zn, } x=2$) alloys in 0.5M HCl solution are shown in Fig. 8. The larger peaks were used to calculate the corrosion current density (i_{corr}), the Tafel slopes (β_c and β_a) and the causality factors (CF^2 and CF^3). These electrochemical parameters are listed in Table IX. The corrosion current density (i_{corr}) of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy decreased after adding Se, In, Al and Zn.

4. CONCLUSION

Microstructure of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy changed after adding Cu, Se, In, Al and Zn contents. Contact angle of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy increased after adding Cu. Melting temperature of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy decreased after adding In contents. Corrosion rate of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy in 0.5M HCl decreased after adding Cu, Se, In, Al and Zn contents. The $\text{Bi}_{48}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}\text{Al}_2$ alloy has lowest corrosion rate. Elastic modulus of $\text{Bi}_{50}\text{Pb}_{25}\text{Sn}_{12.5}\text{Cd}_{12.5}$ alloy increased but Vickers hardness decreased after adding Cu, Se, In, Al and Zn contents.
